AVL Trees, B-Trees

Data Structures and Algorithms

Dr. Nguyen Ho Man Rang Faculty of Computer Science and Engineering University of Technology, VNU-HCM

Outcomes

- L.O.3.1 Depict the following concepts: binary tree, complete binary tree, balanced binary tree, AVL tree, multi-way tree, etc.
- L.O.3.2 Describe the strorage structure for tree structures using pseudocode.
- L.O.3.3 List necessary methods supplied for tree structures, and describe them using pseudocode.
- L.O.3.4 Identify the importance of "blanced" feature in tree structures and give examples to demonstate it.
- **L.O.3.5** Identity cases in which AVL tree and B-tree are unblanced, and demonstrate methods to resolve all the cases step-by-step using figures.

AVL Trees, B-Trees

Dr. Nguyen Ho Man Rang

AVL Tree Concepts

AVL Balance

AVL Tree Operations

Multiway Trees

Outcomes

- L.O.3.6 Implement binary tree and AVL tree using C/C++.
- L.O.3.7 Use binary tree and AVL tree to solve problems in real-life, especially related to searching techniques.
- L.O.3.8 Analyze the complexity and develop experiment (program) to evaluate methods supplied for tree structures.
- L.O.8.4 Develop recursive implementations for methods supplied for the following structures: list, tree, heap, searching, and graphs.
- L.O.1.2 Analyze algorithms and use Big-O notation to characterize the computational complexity of algorithms composed by using the following control structures: sequence, branching, and iteration (not recursion).

AVL Tree

Definition

AVL Tree is:

- A Binary Search Tree,
- in which the heights of the left and right subtrees of the root differ by at most 1, and
- the left and right subtrees are again AVL trees.

Discovered by G.M.Adel'son-Vel'skii and E.M.Landis in 1962.

AVL Tree is a Binary Search Tree that is balanced tree.

BK TP.HCM

AVL Tree Concepts

AVL Balance AVL Tree

Operations

Multiway Trees

B-Trees

A binary tree is an AVL Tree if

- Each node satisfies BST property: key of the node is greater than the key of each node in its left subtree and is smaller than or equals to the key of each node in its right subtree.
- Each node satisfies balanced tree property: the difference between the heights of the left subtree and right subtree of the node does not exceed one.

AVL Tree

Balance factor

- left_higher (LH): $H_L = H_R + 1$
- equal_height (EH): $H_L = H_R$
- right_higher (RH): $H_R = H_L + 1$

 $(H_L, H_R:$ the heights of left and right subtrees)

Why AVL Trees?

When data elements are inserted in a BST in sorted order: 1, 2, 3, ...
 BST becomes a degenerate tree.
 Search operation takes O(n), which is inefficient.

- It is possible that after a number of insert and delete operations, a binary tree may become unbalanced and increase in height.
- AVL trees ensure that the complexity of search is $O(log_2n)$.

AVL Tree Operations

Multiway Trees

Balancing Trees

- When we insert a node into a tree or delete a node from a tree, the resulting tree may be unbalanced.
 - \rightarrow rebalance the tree.
- Four unbalanced tree cases:
 - left of left: a subtree of a tree that is left high has also become left high;
 - right of right: a subtree of a tree that is right high has also become right high;
 - right of left: a subtree of a tree that is left high has become right high;
 - left of right: a subtree of a tree that is right high has become left high;

AVL Delete Algorithm

The AVL delete follows the basic logic of the binary search tree delete with the addition of the logic to balance the tree. As with the insert logic, the balancing occurs as we back out of the tree.

Algorithm AVLDelete(ref root <pointer>, val deleteKey <key>, ref shorter <boolean>, ref success <boolean>)

This algorithm deletes a node from an AVL tree and rebalances if necessary.

Pre: root is a pointer to the root of the [sub]tree deleteKey is the key of node to be deleted

Post: node deleted if found, tree unchanged if not found
shorter is true if subtree is shorter
success is true if deleted, false if not found

Return pointer to root of (potential) new subtree

Algorithm splitNode(val node <pointer>, val entryNdx <index>, ref upEntry <entry>)
Node has overflowed. Split node. No duplicate keys allowed.

Pre: node is pointer to node that overflowed. entryNdx contains index location of parent. upEntry contains entry being inserted into split node.

Post: upEntry now contains entry to be inserted into parent.

```
minEntries = minimum number of entries allocate (rightPtr)
// Build right subtree node
if entryNdx <= minEntries then
| fromNdx = minEntries + 1
else
```

Multiway Trees

Algorithm insertEntry(val node <pointer>, val entryNdx <index>, val newEntry <entry>) Inserts one entry into a node by shifting nodes to make room.

Pre: node is pointer to node to contain data. entryNdx is index to location for new data. newEntry contains data to be inserted.

Post: data has been inserted in sequence.

shifter = node->numEntries + 1

end

 $node->entries[shifter] = newEntry \\ node->numEntries = node->numEntries + 1 \\ return$

Reflow

For each node to have sufficient number of entries:

- Balance: shift data among nodes.
- Combine: join data from nodes.

```
B-Tree Traversal
```

Algorithm BTreeTraversal (val root <pointer>)

Processes tree using inorder traversal.

Pre: root is pointer to B-Tree.

Post: Every entry has been processed in order.

scanCount = 0

ptr = root->firstPtr

while scanCount <= root->numEntries **do**

if ptr not null then

BTreeTraversal(ptr)

end

 $\mathsf{scanCount} = \mathsf{scanCount} + 1$

if scanCount <= root->numEntries then

process (root->entries[scanCount].data)
ptr = root->entries[scanCount].rightPtr

end

end

return

End BTreeTraversal

B-Tree Search

Algorithm BTreeSearch(val root <pointer>, val target <key>, ref node <pointer>, ref entryNo <index>)

Recursively searches a B-tree for the target key.

Pre: root is pointer to a tree or subtree target is the data to be located

Post:

if found — node is pointer to located node entryNo is entry within node if not found — node is null and entryNo is zero

Return found <boolean>

B-Tree Variations

 B*Tree: the minimum number of (used) entries is two thirds.

- B+Tree:
 - Each data entry must be represented at the leaf level.
 - Each leaf node has one additional pointer to move to the next leaf node.
